Abstract: This study examined the influence of gender and science anxiety on students’ academic achievement in basic science at the Junior Secondary School level. The population for this study comprised the Junior Secondary III (JSIII) students in Ogun State Junior Secondary Schools. The sample was One hundred and twenty (120) students drawn from intact classes of the three randomly selected Junior Secondary Schools in three Local Government Areas of Ogun state. Achievement Test for Basic Science Students, and Science Anxiety Scale were the main instruments used to collect data from students. Descriptive statistics, and Univariate Analysis of Variance (ANOVA), were used to analyse the data collected. There was significant main effect of science anxiety on the students’ academic achievement mean scores in basic science at 0.05 level of significance. There was no significant effect of gender on students’ academic achievement in basic science. There was no significant interaction effect of gender and science anxiety on the academic achievement of students. Based on the findings, the authors proffered useful recommendations.

Keywords: anxiety, basic science, gender, science anxiety, students’ achievement.

INTRODUCTION

Science education plays a vital role in the lives of individuals and the development of a nation scientifically and technologically [7]. It is widely and generally acknowledged that the gateway to the survival of a nation scientifically and technologically is scientific literacy which can only be achieved through science education. Towards revolutionizing Nigerian educational system, the 1969 Conference gave birth to the National Policy on Education which brought about significant changes to the Nigerian educational system [7]. For instance, in Nigeria, the National Policy on Education (2004) provided educational expenditure in science and technology. The Nigerian government, in a bid to enhance science and technological education, came up with 6-3-3-4 policy on education which stipulates that a child spends six years at the primary school level, three years at the Junior Secondary School level, three years at the Senior Secondary School level, and four years in Higher Institutions [36]. All the aforementioned systems of education in Nigeria are designed with special provisions for science and technology learning in schools. Moreso, Nigerian government also came up with a policy that 60 percent of the students seeking admission into the nation’s Universities, Polytechnics, and Colleges of Education should be admitted for science oriented courses, while 40 percent of the students should be considered for Arts and social science courses [4].

Basic science, formerly known as Integrated Science, is the first form of science a child comes across at the secondary school level; hence basic science prepares students at the Junior Secondary School level for the study of core science subjects at the Senior Secondary School level [36]. This implies that for a student to be able to study single science subjects at the Senior Secondary School level successfully, such student had to be well grounded in basic science at the Junior Secondary School level. In view of this, basic science is given great emphasis in the Junior Secondary School curriculum. In an attempt to improve the standard of science teaching and learning, a lot of research studies had been carried out. Studies in Basic science education have reported that many students at the Junior Secondary School level have developed negative attitudes toward the subject [5]. Many of the students at this level, because of their dismal performance in the subject, are not benefiting much from the basic science curriculum [2, 3, 10, 35, 37, 38]. This, according to [3], has prevented many of them from offering core science subjects or performing better in the core science subjects at the Senior Secondary School level. Many research studies had been carried out on the effective teaching and learning of basic science. Many of those studies found, among other things, that lack of qualified basic science teachers; methods of teaching; lack of instructional materials;
lack of practical works, etc. are the logics behind students’ dismal academic achievement in Basic Science. Many of the aforementioned studies did not include in their findings the possible effect of science anxiety and gender on students’ academic achievement in basic Science. Conducting this present study would, therefore, not only be appropriate but indeed worthwhile. It is against this background that the present research work examined the effect of science anxiety and gender on students’ academic achievement in Basic Science.

Hypothesis
The following null hypotheses were formulated and tested for this study:

$H_0_1$: There is no significant main effect of science anxiety on academic achievement of students in basic science.

$H_0_2$: There is no significant main effect of gender on academic achievement of students in basic science.

$H_0_3$: There is no significant interaction effect of gender and science anxiety on students’ academic achievement in basic science.

METHODOLOGY
This study employed quasi-experimental design. The target population for this study was the Junior Secondary III (J.S.III) students in Ijebu-Ode, Ijebu North – East, and Odogbolu Local Government areas of Ogun State, South-West Nigeria. The sample for this study was the total number of one hundred and twenty students (120) students in the intact classes used in the selected co-educational Junior Secondary Schools. Stratified random sampling was used to select three co-educational Junior Secondary Schools from the total number of co-educational Junior Secondary Schools in the aforementioned local government areas. Achievement Test for Basic Science Students (ATBSS) and Science Anxiety Scale (SAS) were the main instruments used for data gathering. The ATBSS was a test of students’ achievement in basic science. The concepts examined were based on the five topics in basic science scheme of works for third term. The test items of forty multiple choice questions were adopted from the past questions of Junior Secondary School Certificate Examination (JSSCE) in basic science in Ogun State. The JSSCE questions are standardized in nature because it has been field-validated by the experienced test and measurement experts in the state ministry of education. Moderating Committee edited and selected good items. Copies of the Achievement Test for Basic Science Students (ATBSS) were given to specialists in the field of science education to establish the content and face validity. Spearman - Brown coefficient was used to determine the reliability coefficient of ATBSS, which was found to be 0.811. The SAS instrument was the adapted 20-item science Anxiety Rating Scale by Murat BURSAL (2008). Two of the 20 items that were not relevant to basic science were discarded; hence the science rating scale contained 18 items. The instrument was to find students’ level of science anxiety for learning science at the Junior Secondary School level in order to categorize them into low and high science anxiety levels respectively. There were two sections in the questionnaire; section A sought for demographic data of students, while section B consisted of 18 items which students responded to by expressing their level of agreement or otherwise on a 5-point Likert-type scale ranging of $1 = No anxiety, 2 = slightly low anxiety, 3 = not sure, 4 = slightly high anxiety, and 5 = High anxiety$. The reliability of the instrument was determined by using Cronbach’s alpha which was found to be 0.968.

There were three phases of data collection. These were the pretest – first one week, treatment – six weeks, and the posttest – one week–last one week of the eight weeks. Three periods of 40 minutes each were spent each week for the six weeks. There was no alteration on the time-table allocated for basic science by the school, i.e. the periods were in line with the schools’ time-tables. Before exposing the selected students for the study to teaching, the students were given the questionnaire on science anxiety for their responses in other to categorize them into low and high anxiety levels respectively. The students were taught using the normal conventional lecture method. At the post-test level, the ATBSS was administered to the students one week after the completion of teaching. The data collected from the administration of the instruments were analyzed using the following statistical techniques: descriptive statistics, which involved the computation of the post-test mean scores; and standard deviation for the dependent variables. Univariate Analysis of Variance (ANOVA) computed for the dependent variable in order to test for possible post experimental differences in the dependent variables with respect to science anxiety, and gender. Computations for the aforementioned methods of data analysis were done using SPSS 15.00 Statistical Package.

Theoretical Framework
Identifying factors that influence student achievement and motivation to learn in the classroom continues to be a goal of education researchers [25]. Classroom climate is sometimes referred to as the learning environment in which the students interact with one another [1], and the classroom climate can affect a student’s motivation, interest, and achievement.
A lot of learning takes place in a stimulating environment when social relations are considered before any other factors. Everyone sometimes experiences anxiety in one form or another and in varying degrees. It involves a pattern of physiological and psychological reactions like feeling of stress and emotions. As such, anxiety can seriously inhibit the ability of concentration and dealing with things in a more positive way. It is considered as an unpleasant state evoking avoided behaviours and defenses. It can also be defined as a specific emotion necessary for an individual to prepare for potential and threatening situations. Many researchers found that anxiety is still unclear and not easy to define in simple sentences [16]. Science anxiety is described as involving feelings of tension and stress that interfere with construction of science knowledge, the development of science skills and abilities, and the use of science knowledge, skills, and abilities in a wide variety of ordinary life and academic situations [40, 43], and can negatively impact cognitive processing [15].

Different sources contributing to science anxiety such as gender stereotyping, misconceptions about the scientific method, and associating science with technology have been identified [43]. Science anxiety in students can be strongly influenced by science anxiety in teacher [43]. Disappointingly, this may be contributing to intergenerational cycle of fear surrounding learning about science. Science anxiety in high school students is inversely correlated with self-esteem. Such feelings are shown to lead to panic, tension, helplessness, fear, distress, shame, inability to cope, sweaty palms, nervous stomach, difficulty in breathing, and loss of ability to concentrate which hamper science achievement [41]. If a student feels that he/she will be penalized for failure, frightened or rejected, such student will find it difficult to concentrate on learning. For optimal learning to take place, classroom climate should be positive and supportive and the behaviour of the teacher, more than any other individual, sets the climate of the class. Teachers can most readily influence climate by focusing on two complementary aspects of classroom interaction – the rapport between teacher and students and the rapport among the students.

**Anxiety and Achievement**

Research findings have revealed anxiety as one of the variables that affect achievement [28, 39, 40, 46]). Some of these studies have associated high anxiety with low achievement. [42] Investigated the effects of mathematics anxiety levels on students’ achievement in mathematics. The researcher used Pearson product moment correlation statistical analysis to analyze data collected to determine if there were any relationships between anxiety levels of the students and their achievement scores. The analysis indicated that as mathematics anxiety scores increased, achievement scores decreased. [8] found that children with high anxiety had significantly lower scores. Similarly, [40] found that anxiety yielded differences in students’ learning outcomes.

**Gender and Achievement**

What has remained the main focus of great concern in the field of science education are the biases and misconceptions about women and science, i.e. Science is a male enterprise [23]. Many researches had been carried out on gender issues in science education [11, 20, 21, 22, 23, 29]. Many researchers have provided reports that there are no longer distinguishing differences in the cognitive, affective and psychomotor skill achievements of students in respect of gender [9, 12, 17, 19, 24]. However, [13, 26, 30] in their studies found that male students performed better than female students in the cognitive, affective and psychomotor skill achievements.

### Result

Table 1. Descriptive statistics of students’ posttest academic achievement mean scores according to anxiety and gender

</table>
In table 1, it is revealed that low anxiety students had the higher posttest (27.50) mean score than their colleagues in the high anxiety group whose posttest mean score was 19.88 (high anxiety implies low mean scores, while low anxiety implies high mean scores). It is also revealed in table 1 that there was slight difference in the post-test mean scores of male (23.66) and female (24.89) students, but the difference was not significant.

H₀₁: There is no significant main effect of science anxiety on academic achievement of students in basic science. It is also revealed in table 2 that there was no significant difference in the posttest mean scores of low and high science anxiety students (F (1,119) = .000, statistically significant). Hence hypothesis 1 is not accepted.

H₀₂: There is no significant main effect of gender on academic achievement of students in basic science. It is also revealed in table 2 that there was no significant difference in the posttest mean scores of male and female students (F (1,119) = .000, statistically significant). Hence hypothesis 2 is accepted.

H₀₃: There is no significant interaction effect of gender and science anxiety level on students’ academic achievement in basic science.

Talking about the interaction effects of anxiety and gender, it is revealed in table 2 that there was no significant interaction effect of gender and anxiety on students’ academic achievement (F (1,119) = 108, statistically not significant).

**DISCUSSION**

This study was conducted to examine the extent to which gender and science anxiety affect students’ academic achievement in basic science at the Junior Secondary school level. Results in tables 1 & 2 indicated that there were differences in the academic achievement mean scores of low science anxiety students and high science anxiety students. This implied that anxiety did affect students’ academic achievement in basic science. As level of science anxiety decreased; achievement scores increased; high science anxiety led to decrease in academic achievement scores. This result is in line with the findings of [8, 18, 20, 23]. Tables 1 & 2 also revealed that students’ academic achievement in basic science was gender invariant. Though there was slight difference in the post-test mean scores of female (24.89) and male (23.66) students, the difference was not significant. This result is also in line [9, 12, 17, 19, 24, 41] who provided reports that there are no longer distinguishing differences in the cognitive, affective and psychomotor skill achievements of students in respect of gender. The low science anxiety male students had higher post-test mean scores (27.97) than their high science anxiety male colleagues (18.65). Similarly, the low science anxiety female students had higher post-test mean scores (26.97) than their high science anxiety female colleagues (21.71). This implies that students with low science anxiety generally understood and improved in their academic achievement in basic science, while reverse was the case with their colleagues with high science anxiety. With respect to the interaction effects of gender and science anxiety, tables 1 & 2 revealed that there was no significant interaction effect of gender and science anxiety on students’ academic achievement. This implies that the effect of anxiety on the students’ academic achievement in basic science was insensitive to their gender. The mean scores of the male – low science anxiety and male – high science anxiety were not significantly different.

Available Online: [http://saspjournals.com/sjahss](http://saspjournals.com/sjahss)
from one another; similarly, the mean scores of the female – low science anxiety and female – high science anxiety students were not significantly different from one another.

**IMPLICATIONS AND RECOMMENDATIONS**

This study has very important contributions and high implication for the educational practices in Nigeria. This study revealed that low science anxiety students had higher academic achievement mean scores than the high science anxiety students. Therefore, basic science teachers should strive to understand science anxiety and implement appropriate teaching and learning strategies which can help the students overcome their science anxiety. This implies that if many of the basic science / science teachers do not make their lessons friendly with the students or are fond of using teaching methods that do not actively involve students in the teaching and learning basic science/science subjects, such sets of students would be afraid to attend such classes; and when they do, they would not concentrate on what their teachers are teaching them. This study also found that gender-related factors do not influence anxiety and academic achievement in Basic science.

Based on the findings of this study, the following recommendations were made:

1. Basic science/science teachers should stop going to the class with cane in hand and establish good rapport with their students. This would enhance students’ interest in the subject and lead to students having positive attitude towards basic science/science subject.
2. When friendliness is established, students are motivated to learn and are more confident to ask questions from one another for better understanding of the tasks being learnt. Hence basic science/science teachers should adopt teaching method(s) that would actively involve students in the teaching and learning process (e.g. cooperative learning strategy, etc).
3. Science/Basic science teachers should demonstrate their own interest in science/basic science in order to raise students’ motivation in science/basic science as a means of helping students reduce their science anxiety.
4. Science/basic science teachers should take into account the science anxiety levels of their students before determining effective and appropriate teaching strategies.
